

# The threshold of toxicological concern (TTC)

-

## a suitable tool for mixture risk assessment?

# The Threshold of Toxicological Concern (TTC)

Generic human exposure threshold value, below which  
**“the probability of adverse effects on human health is  
considered to be very low. ”**

# The Threshold of Toxicological Concern (TTC)

**The TTC is the lower 5% percentile** of a pool of log-normally distributed NOELs, divided by an AF of 100.

*S. Barlow, Threshold of Toxicological Concern, ISLI Monograph Series, 2005.*  
*After: Munro IC, et al.; Food Chem Tox, 34. 829-867, 1996*

# Consequences of using the lower 5% percentile

- ❑ 5% risk that any one given compound has a  $\text{NOEL}/100 < \text{TTC}$  (risk for misclassification, risk of a false-negative)
- ❑ Obviously: the more compounds, the higher the risk of misclassification
- ❑ Mathematically speaking:

$$1 - 0.95^n$$

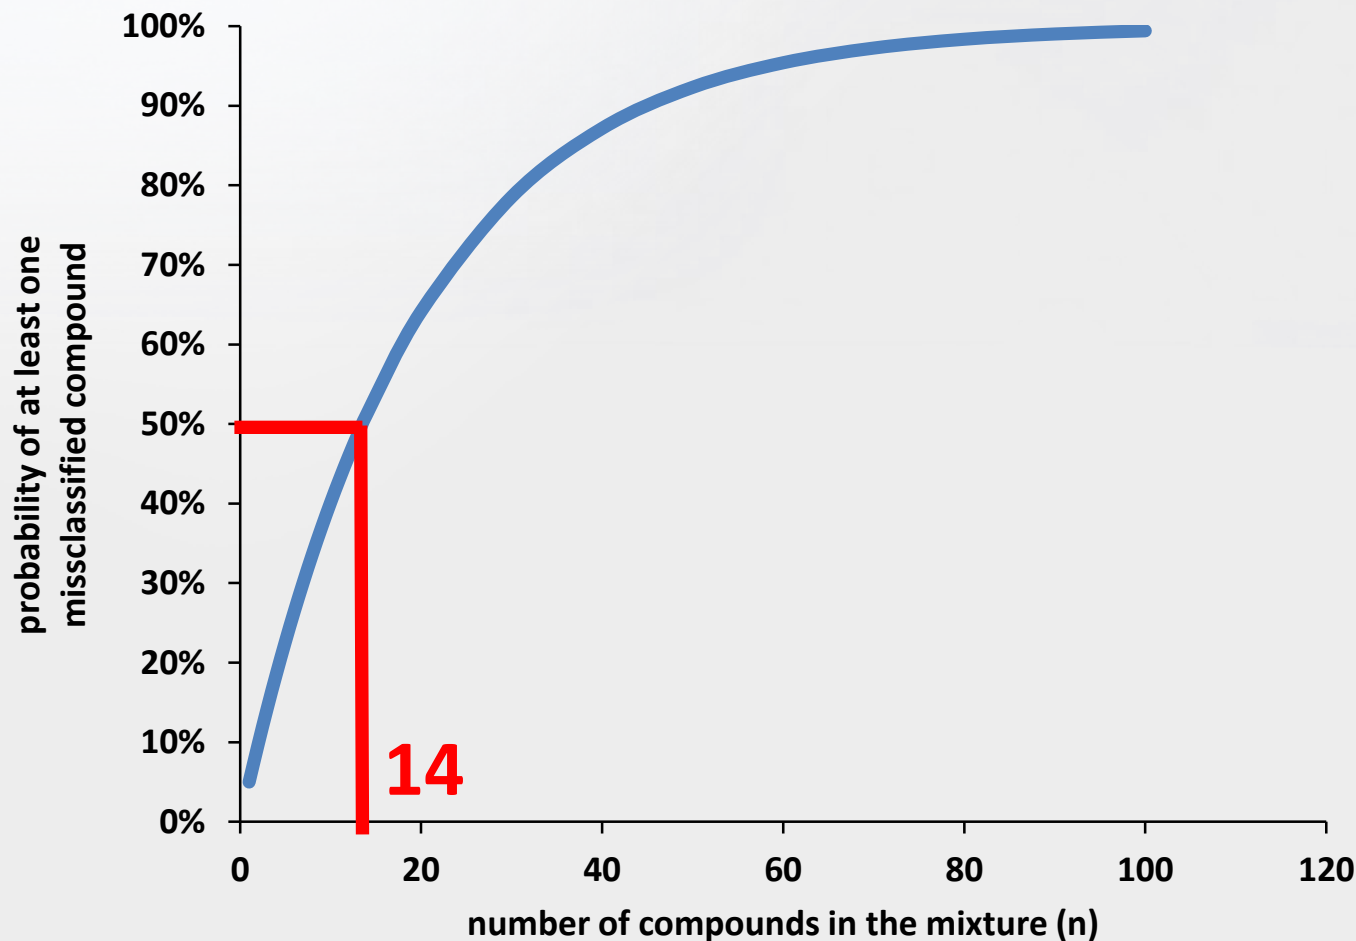

# Consequences of using the lower 5% percentile

# Consequences of using the lower 5% percentile

# Consequences of using the lower 5% percentile

- ❑ 5% risk that a given compound has a  $\text{NOEL}/100 < \text{TTC}$
- ❑ Obviously: the more compounds, the higher the risk of misclassification

- ❑ Mathematically speaking:

$$1 - 0.95^n$$

- ❑ In a 14 compound mixture there is a 50% risk that at least one misclassified compound is present.

n	Risk of misclassification
10	40%
20	64%
30	79%
40	87%
50	92%

# Which percentile to achieve an overall misclassification risk of $\leq 5\%$ ?

- ❑ Depends on the number of compounds
- ❑ Mathematically speaking:

$$1 - 0.95^{1/n}$$

# Which percentile to achieve an overall misclassification risk of $\leq 5\%$ ?

# Which percentile to achieve an overall misclassification risk of $\leq 5\%$ ?

# Which percentile to achieve an overall misclassification risk of $\leq 5\%$ ?

❑ Depends on the number of compounds

❑ Mathematically speaking:

$$1 - 0.95^{1/n}$$

❑ In a 20 compound mixture the lower 0.26% percentile needs to be used in order to ensure an overall misclassification risk of 5%.

n	percentile
10	0.51%
20	0.26%
30	0.17%
40	0.13%
50	0.10%

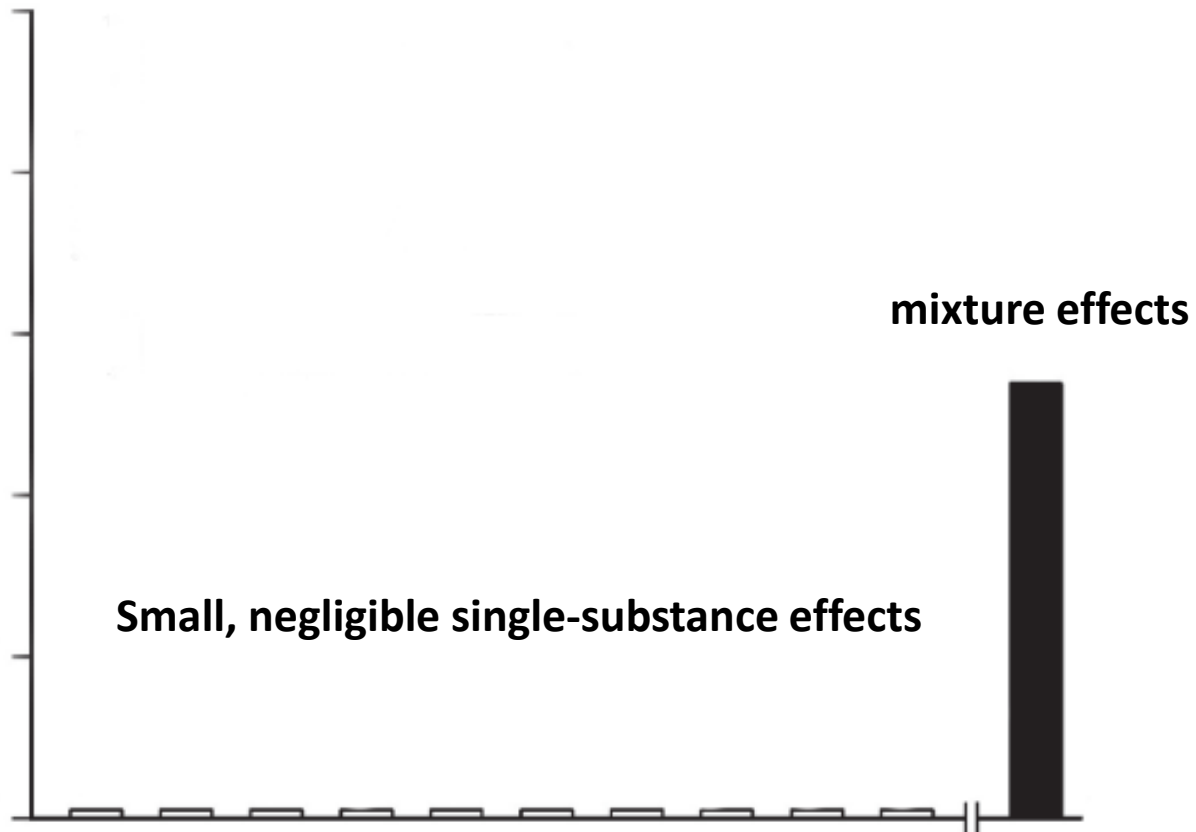

# Why are mixtures of specific concern?

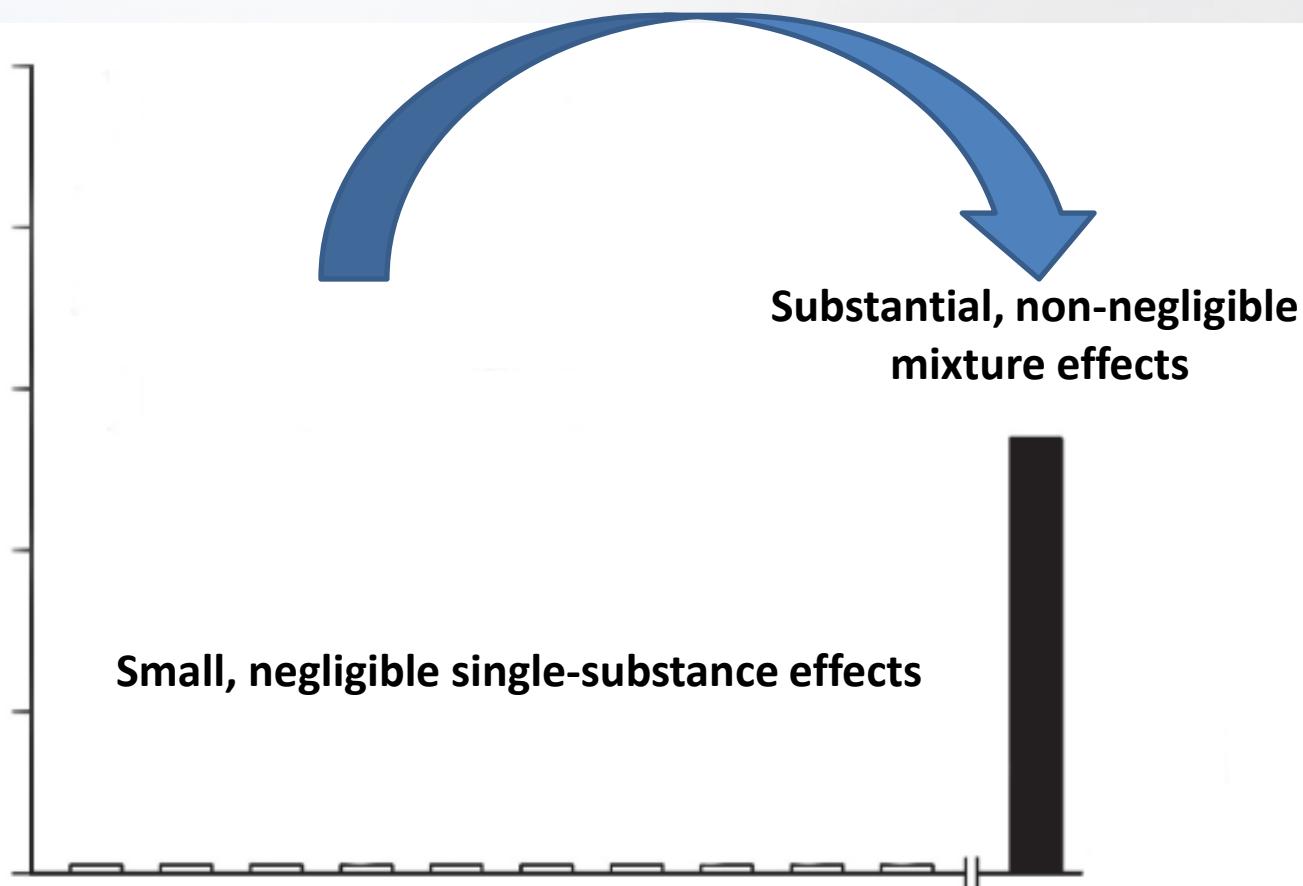

# Why are mixtures of specific concern?

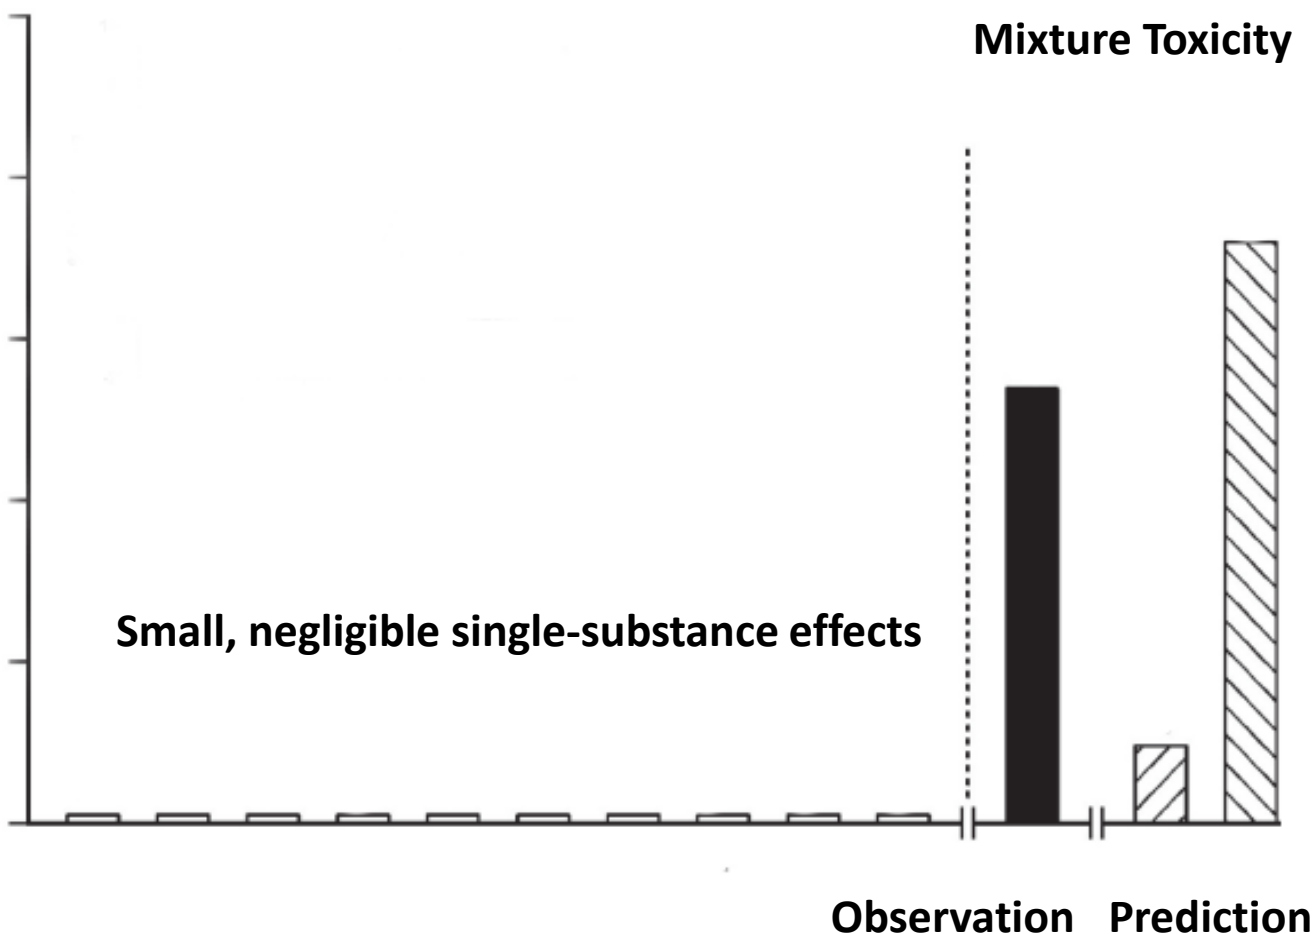

# Why are mixtures of specific concern?

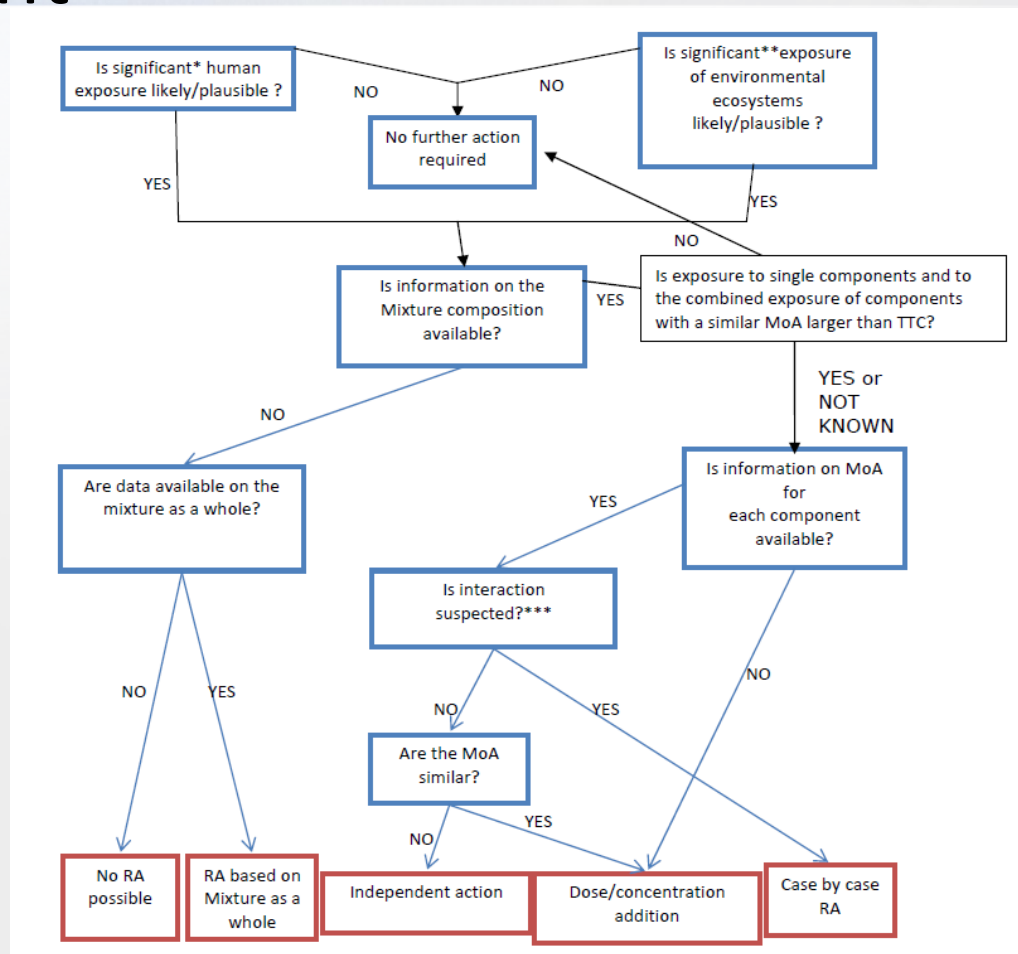

# Why are mixtures of specific concern?

# Why are mixtures of specific concern?

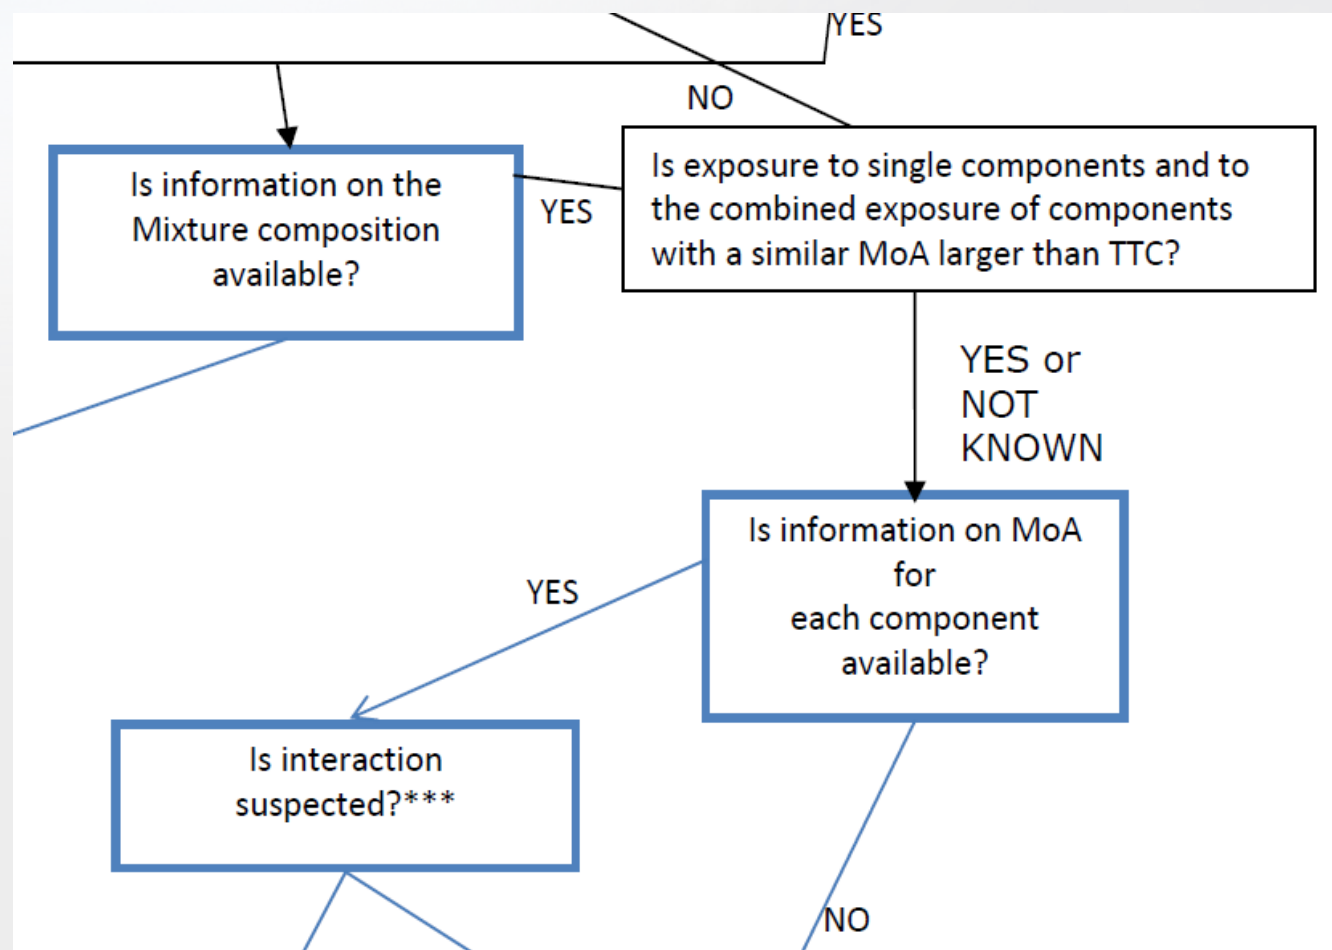

- ☐ Mixture toxicity is higher than the toxicity of each compound at the concentration present in the mixture
- ☐ Compliance with individual threshold values (ADI, TDI, TTC) does not necessarily safeguard against unwanted mixture effects

# Suggested use of the TTCs in mixture risk assessment

*(Scientific Opinion on Mixture Toxicity Assessment, SCHER, SCENIHR, SCCS)*

# Suggested use of the TTCs in mixture risk assessment

*(Scientific Opinion on Mixture Toxicity Assessment, SCHER, SCENIHR, SCCS)*

# Suggested use of the TTCs in mixture risk assessment

- ☐ Compounds with dissimilar modes of action do not contribute to the mixture toxicity if present below their individual TTC
- ☐ If exposure to compounds with dissimilar modes of action is below their individual TTC, there is no mixture risk  $>$  TTC

# Mixture toxicity concepts

## Similarly acting substances: Concentration Addition

$$ECx_{(Mix)} = \left( \sum_{i=1}^n \frac{p_i}{ECx_i} \right)^{-1}$$

- $c_i$  = Concentration of component  $i$  in the mixture ( $i = 1 \dots n$ )
- $ECx_i$  = Concentration of substance  $i$  provoking a certain effect  $x$  when applied alone
- $ECx_{(Mix)}$  = Predicted total concentration of the mixture, that provokes  $x\%$  effect.
- $p_i$  = relative fraction of component  $i$  in the mixture

## Dissimilarly acting substances: Independent Action

$$E_{Mix} = 1 - \prod_{i=1}^n (1 - E_i)$$

- $E_{Mix}$  = Effect of the mixture of  $n$  compounds
- $E_i$  = Effect of substance  $i$ , when applied singly

# TTCs and Independent Action

$$E_{Mix} = 1 - \prod_{i=1}^n (1 - E_i)$$

$$E_{Mix} = E_1 + E_2 - E_1 \times E_2$$

If  $E_1=0$  AND  $E_2=0$  then  $E_{Mix}=0$ ,

$$\text{Ergo: } TTC_{Mix} = \min \left( \frac{TTC_i}{p_i} \right)$$

# TTC and IA and some pitfalls

- ☐ TTC must actually describe a true zero-effect concentration if IA is supposed to safeguard against unwanted mixture effects
- ☐ We know that NOELs are no true zero-effect concentrations
- ☐ How about the lower 5% percentile of a log-normal distributed collection of NOELs divided by an Assessment Factor of 100?

# Are TTCs true zero effect levels?

**Truly Zero = no effect on a molecular level**

$$v = \frac{V_{\max} \times [c]}{K_M + [c]}$$

# TTC and IA and some pitfalls

- ❑ TTC must actually describe a true zero-effect concentration,
- ❑ AND the compounds must be completely independently acting

... if IA is supposed to safeguard against unwanted mixture effects at individual concentrations  $< \text{TTC}$

## Independent Action

Bliss, 1939:

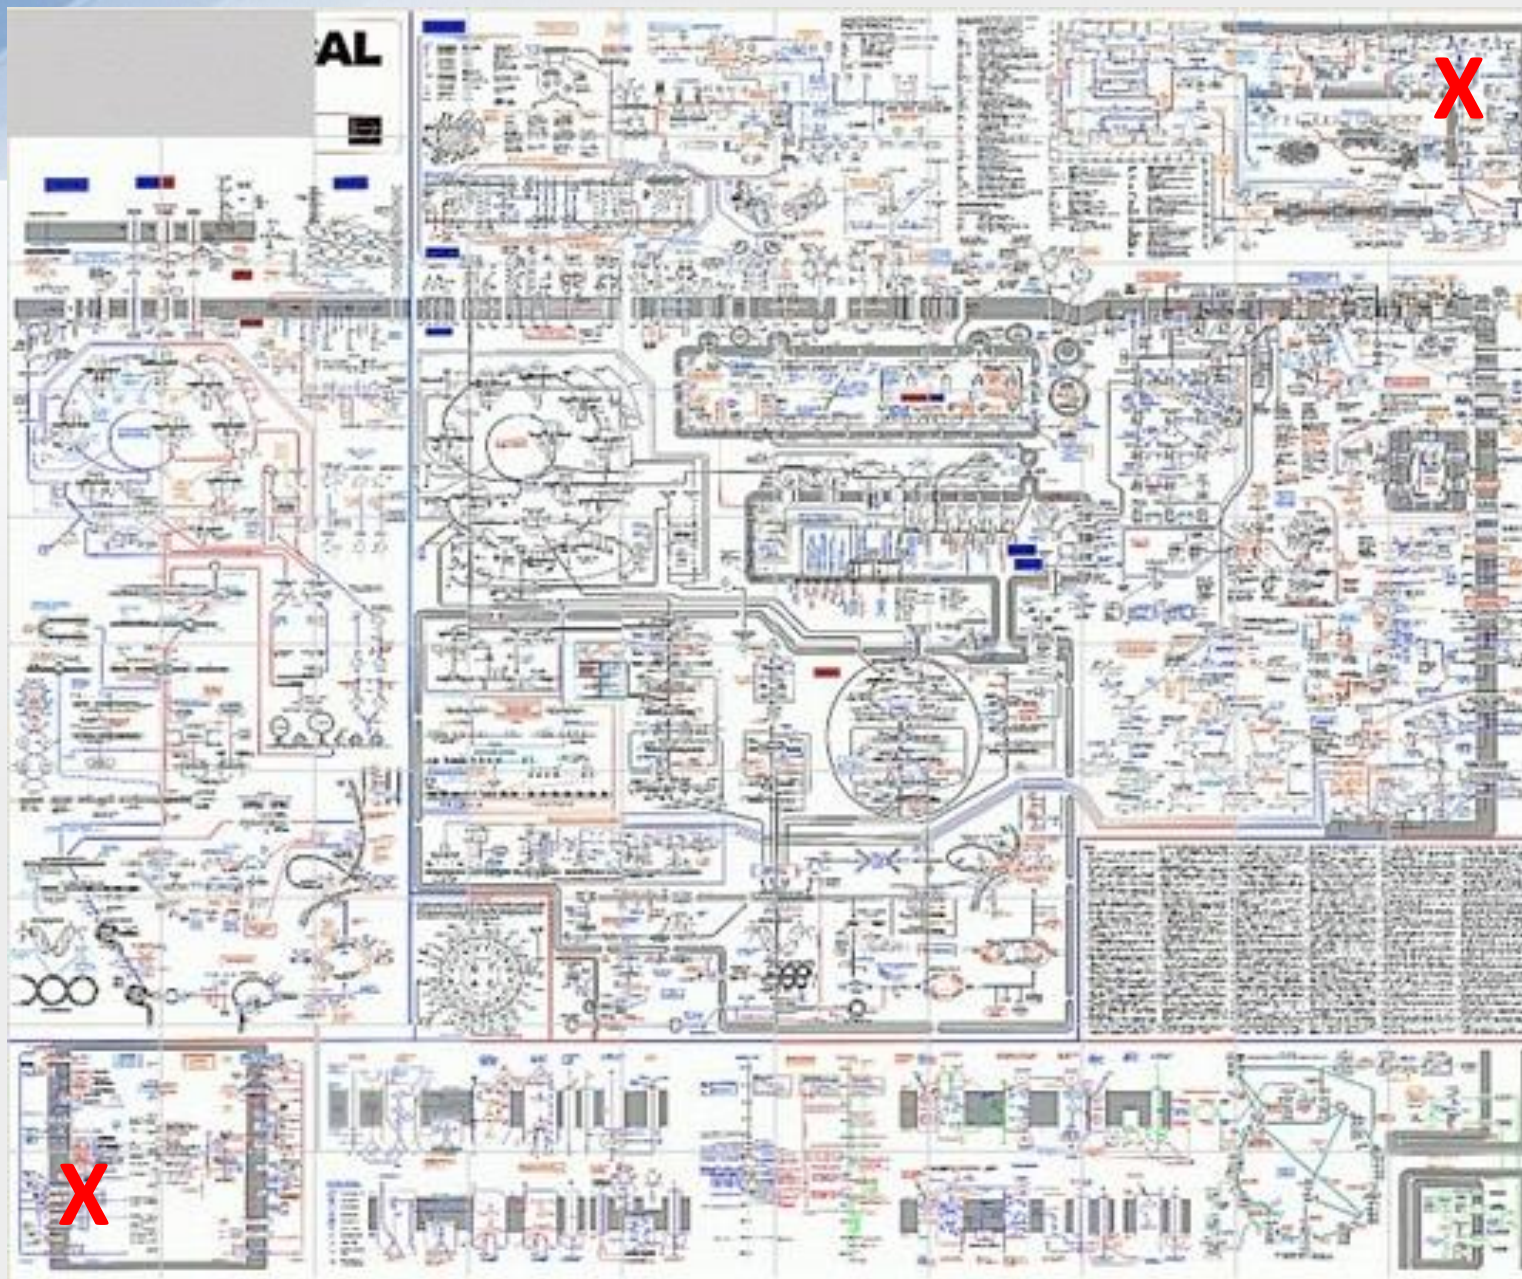

## Independent Action

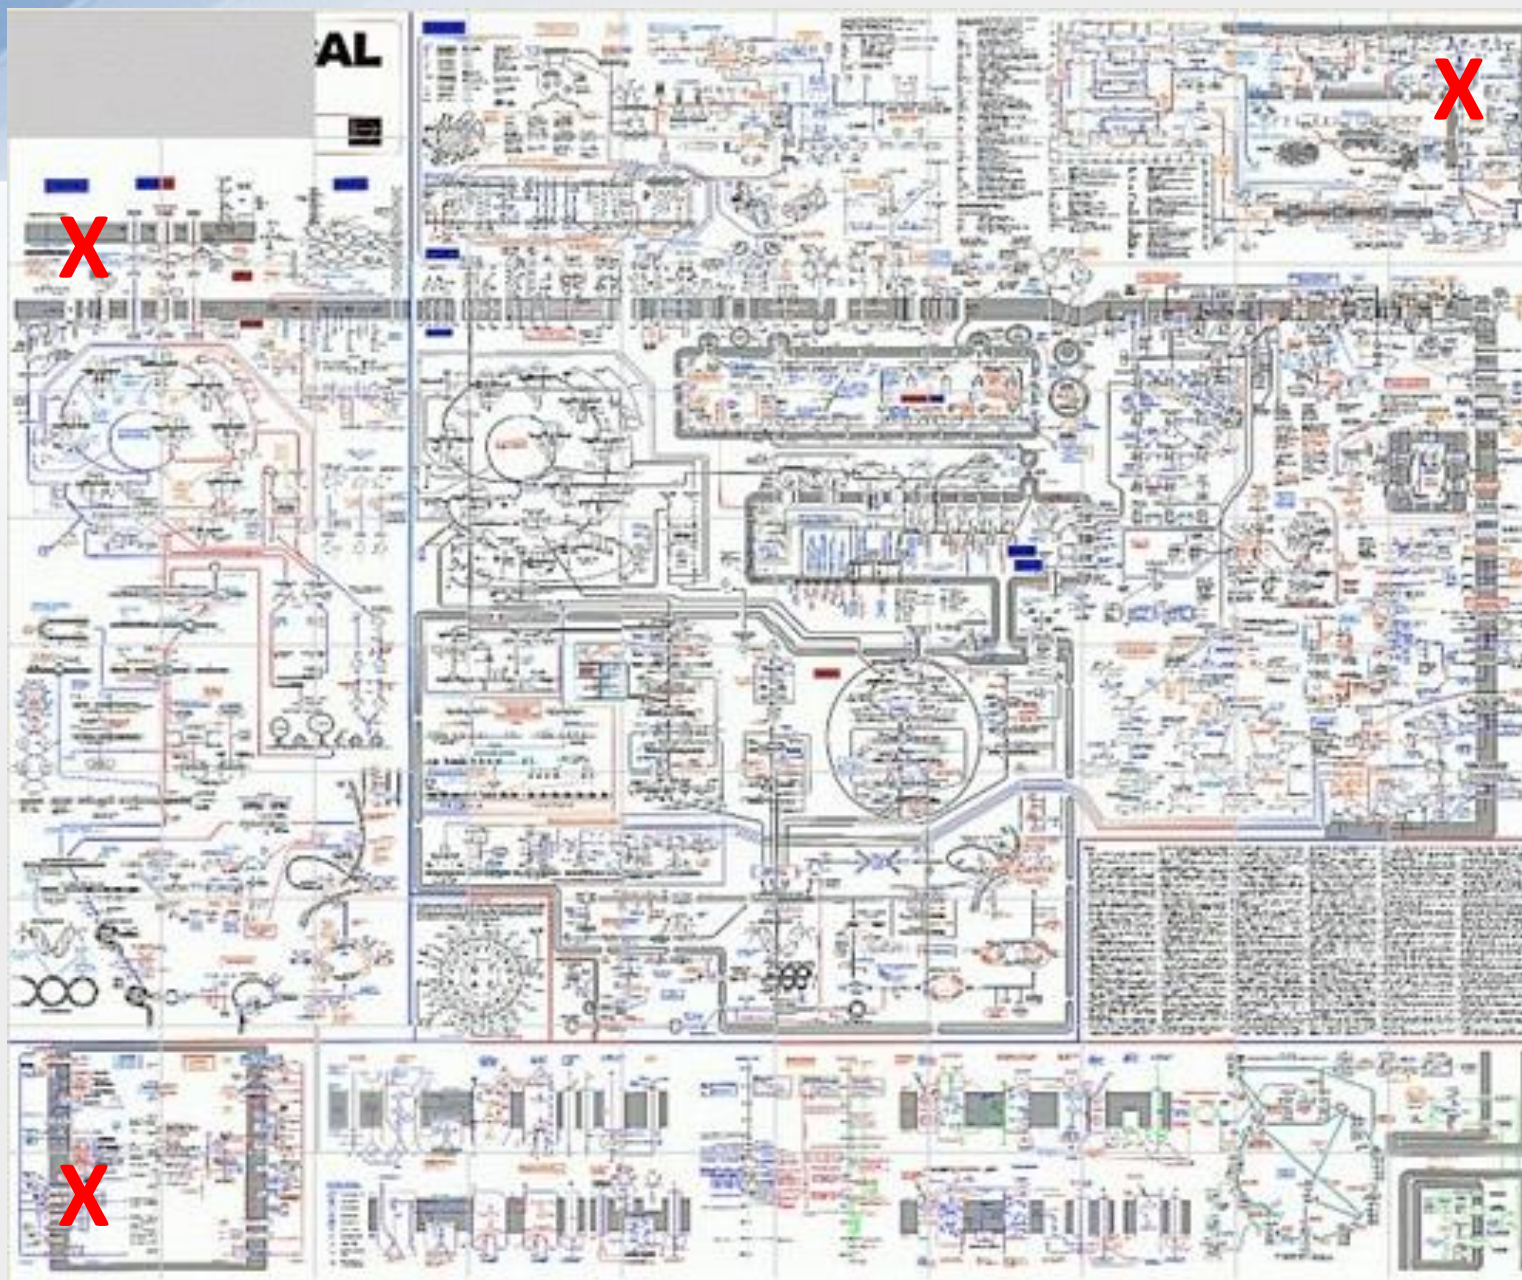

One toxicant does not influence the toxicity of another one.

## Suggested use of the TTC concept in mixture risk assessment

*(Scientific Opinion on Mixture Toxicity Assessment, SCHER, SCENIHR, SCCS)*

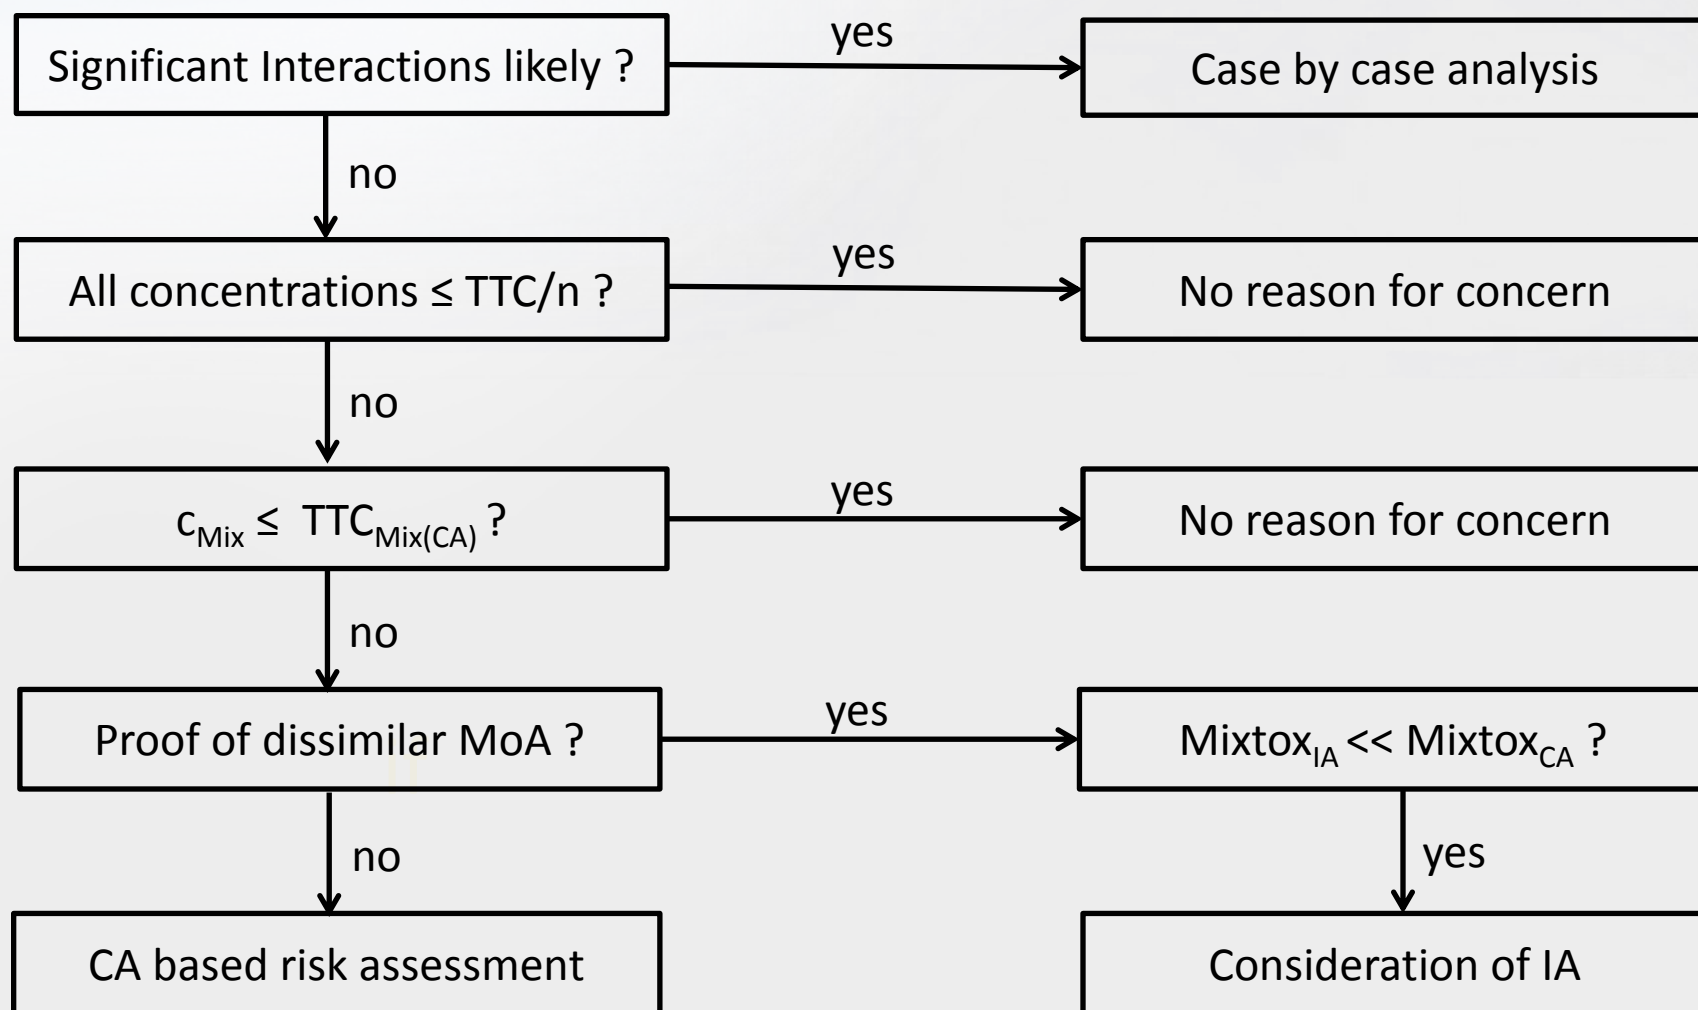

# TTC and Concentration Addition

$$TTC_{Mix} = \left( \frac{p_1}{TTC_1} + \frac{p_2}{TTC_2} \right)^{-1}$$

$$E_{TTC} \geq E(Mix)$$

$$\text{if } c_i \leq \left( \frac{TTC_i}{n} \right)$$

# Suggested use of TTC for mixture risk assessment

# Summary and conclusions

- ❑ The use of the lower 5% percentile leads to an inflated misclassification risk for mixtures  
(misclassification risk = risk that at least one of the compounds has a  $\text{NOEL}/100 < \text{TTC}$ ).
- ❑ In order to keep the misclassification risk at 5%, the percentile needs to be adjusted accordingly (roughly divided by  $n$ ).

# Summary and conclusions

- ❑ Mode of Action driven mixture assessments are very data demanding.
- ❑ IA is of very limited use
- ❑ The application of IA does not allow the conclusion that mixture effects are absent at low doses
- ❑ Use CA for estimating the mixture TTC ( $\sim \text{TTC}/n$ )
- ❑ Incorporation into a tiered approach
